

Achieving bidirectional transmission over a single fiber

Overview

This comprehensive guide explains how WDM couplers combine and separate different wavelengths (1310nm/1550nm, 1270nm/1330nm, 850nm/900nm) to achieve bidirectional transmission on one fiber strand—cutting fiber usage by 50% while maintaining performance. A key design consideration in optical networks is how data is transmitted through the fiber: either in a single direction (one-way transmission) or in both directions over the same fiber (bidirectional communication). Simple design and low requirements. Easy fault isolation. Bidirectional over Single Fiber (BiDi) means that data transmission and reception can be completed simultaneously within a single optical fiber, unlike ordinary optical fibers which use two separate wires for transmission and reception. Understanding the role of BiDi optical modules requires recognizing their significance in facilitating streamlined.
